Abstract

Blood being one of the most important connective tissues, hematological study was done after isolating blood sample from Bt cry protein fed rats thereby determining the effect of the protein if any. Blood cell count was done by using Neubauer's Haemocytometer slide and it was observed the total count of erythrocytes gradually decreased as compared to the control. This can be either by, degrading RBCs or by, causing an infection. Study on differential count of leukocytes showed that there was an increase in the neutrophil, eosinophil and monocyte count in blood along with a drastic decline in basophil count as compared with the control. This might again be an indication of certain infection in the toxin fed rats as neutrophil, eosinophil & monocyte acts as a first responder to infection. Further, the PBMCs (Peripheral Blood flow Mononuclear Cells) showed that normal morphology of monocytes and lymphocytes were distorted. The cells were found to be ruptured and the degraded cell membrane had certain black dots that are yet to be inferred.

Keywords: Bacillus Thuringiensis (Bt), Cry Protein, TC, DC, Gradient Centrifugation, Neutrophil, Monocyte

Introduction

Cry proteins are specifically toxic to several insect orders like Lepidoptera, Coleoptera, Hymenoptera and Diptera, and also to nematodes. The Cry proteins comprise at least 50 subgroups with more than 200 members. Cry proteins are defined as: a parasporal inclusion protein from Bt that exhibits toxic effects to a target organism, or any protein that has obvious sequence similarity to a known Cry protein [1]. A previous study explains Cry toxins exert their toxicity when activated at alkaline pH of the digestive tract of exposed larvae, and, because the somatic morphology of the digestive system in mammalian body does not allow the activation. However, the study demonstrated that Bt spore-crystals induced hematotoxicity, particularly to the erythroid ancestry. Bt spore-crystals caused haemolysis in cell lines of rat, mouse, sheep, horse, and human erythrocytes and suggested that the plasma membrane of vulnerable cells (erythrocytes in this case) may be the primary target for these toxins [2].

Bt spore-crystals can induce haematological problems in vertebrates, and their toxicity increases with time [3-5]. According to the studies carried out, aggrandized work is needed to understand the mechanism behind the hematotoxicity seen in mice.

Experimental Design and Structure

The design of the experiment carried out for analysis is described below (Fig.2.1)

Result of Histopaque Gradient PBMC Isolation

As shown in the figures the PBMC isolation showed that after the treatment of Bt cry protein the buffy layer containing monocytes and lymphocytes has decreased significantly.

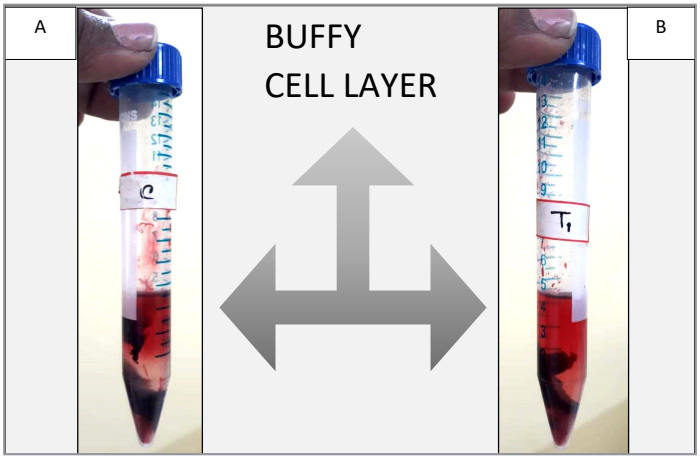

Figure 8: HISTOPAQUE-1077 Gradient Centrifugation
PBMC cell layer for the control and treated rats respectively. The control(A) centrifuge tube denoting the buffy layer i.e. the monocyte and lymphocyte layer is higher than the centrifugedenoting the same for treated rat (B).

Observation after Staining of the Monocytes & Lymphocytes
As shown in the figures the PBMC isolation showed that after the treatment of Bt cry protein the buffy layer containing monocytes and lymphocytes was taken and centrifuged as described previously and stained with Leishman staining procedure the following results were observed-

- The control rat's blood sample showed that the lymphocytes are not in particular shape and with degenerated morphological appearance.
- After treatment the treated rat showed that the monocytes have black dots in its membrane differing significantly from the normal ones.

Conclusions, Outlook and Future Aspects

In conclusion, the results obtained from this study, gives several information that can be summarized as total count of RBC is decreased in Bt cry protein treated rat as compared to untreated rat while differential count of WBC exhibit an increase in % count of neutrophil, eosinophil and monocyte thus gives a statistically significant difference, on the other end, decline in basophil and lymphocyte count observed in treated rat than control, thus can be concluded that Bt cry protein may be induces infections in treated rats as well as low count of RBC also fortified this as it may be degraded or causing infection with in rat [6-15].

In addition to this, through biochemical analysis it was observed that the levels of bilirubin, SGPT, SGOT are decreased significantly in blood in the treated group from the control. Other serum enzymes such as ALP increased significantly in blood of treated animal and Catalase activity decreased significantly for the same than control [16-21].

Though these deductions conclude that Cry proteins might give rise to certain inflammatory symptoms further investigations are needed in this area to explore the mechanism and to determine the cytotoxicity of Cry proteins in mammalian tissues [22-26].

Acknowledgements

We are very grateful to our Principal Dr. Jayashree Laha for providing us with the Laboratory and we are equally grateful to our institution Raja Narendra Lal Khan Women's College autonomous for sole assistance and the supporting environment.
